HTML Forms

HTML forms are used to collect user input. To make a form in HTML you need to use <form> tag. The user input is most often sent to a server for processing. The form tag is used to create an HTML form for user input.

Form can contain input elements like text fields and labels for these fields.

example:

As you see in the example the value in for in the label element should be exactly the same as the value in id of the input field.

Each input field should have a name attribute to be able to be sent to the server.

Sometimes you want the user to enter a password, an email, a phone number, a date, a color, a number, etc. HTML5 has a lot of new input types for these cases. Just use the type attribute to specify the type of input.

There is a lot of input types, some of them are:

- text
- password
- email
- number
- date

- color
- url
- tel
- search
- file

Example:

HTML FORMS

Each input element should have a name, type attributes.

You can also add the value attribute to set the default value of the input field.

The submit button is used to send the form to the server and it has a submit type.

The
br> used in the example above is used to add a line break between the input fields.

To allow uploading files you can use the file type, and to allow multiple files you can use the multiple attribute.

You can also allow only a specific type of files using the accept attribute.

Example:

To allow any type of images you can use accept="image/*". See this link for more information.

The button element has a type attribute that can be submit, reset, or button.

- submit: The button submits the form data to the server. (This is the *default*)
- reset: The button resets all the form data to its initial values.
- button: The button does nothing.

You can also use a regular input tag instead of button and set the type attribute to submit, reset, or button, but it's better to use the button tag.
